New SIDRA Training Workshops (In-Person) 2023

We have designed new programs for in-person (classroom) training.

- **SIDRA Advanced Workshop**

New in-person (classroom) workshop for users of SIDRA INTERSECTION software.

- **SIDRA for Project Managers & Reviewers**

For professionals who review SIDRA analyses rather than actually undertaking the analyses, as well as project managers who have little experience in modelling but make design and operation decisions based on review of SIDRA analyses.

Dates

- **SYDNEY | 28-31 March 2023** 
- Brisbane | 11-14 July 2023
- Perth | 8-11 August 2023
- Melbourne | 22-25 August 2023

SIDRA NETWORK MODEL

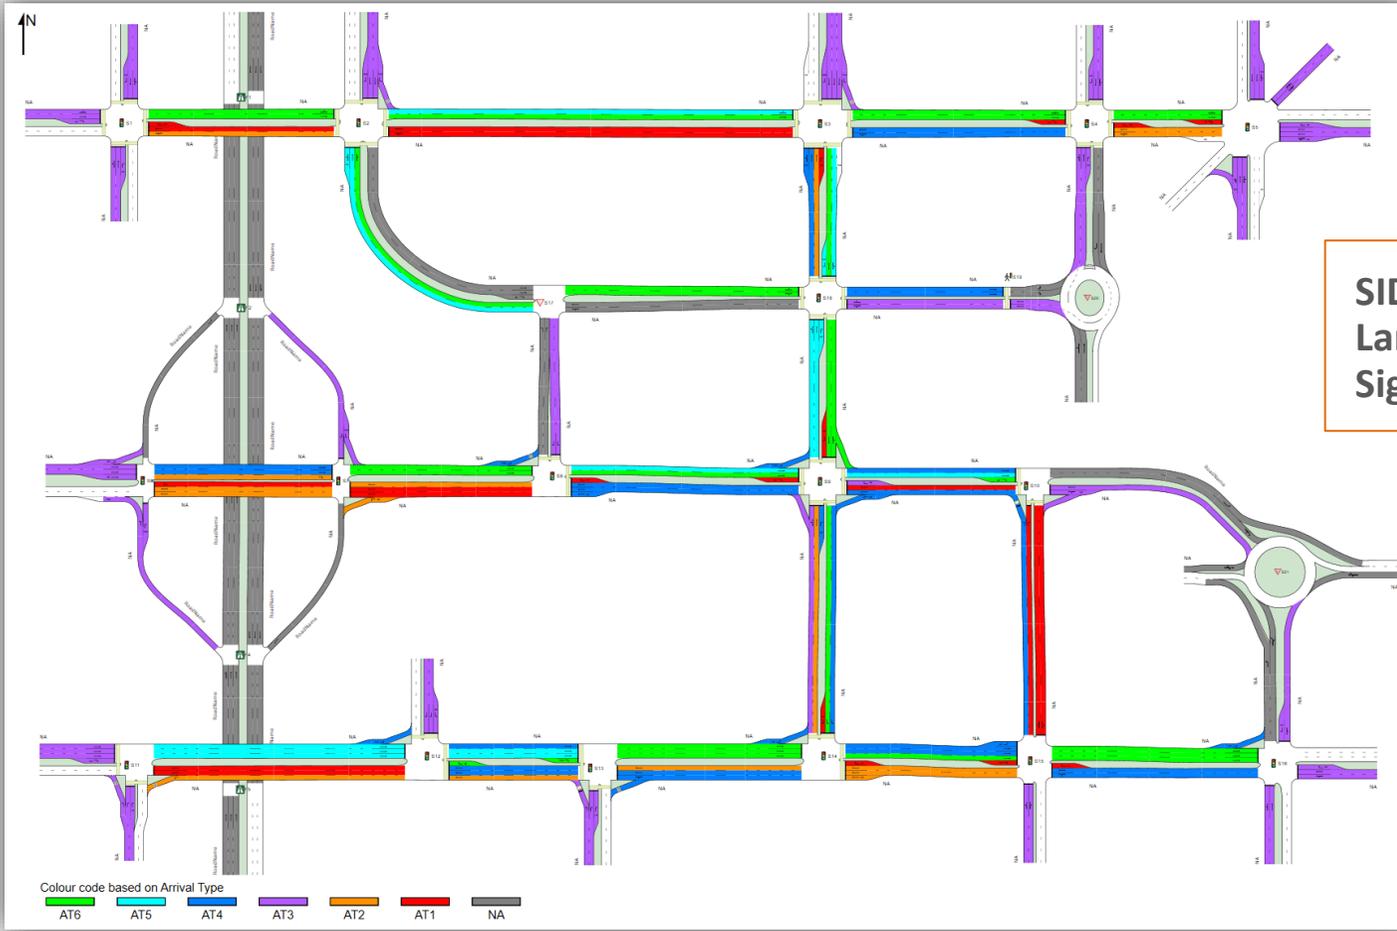

SIDRA Network Model

Lane-based micro-analytical model

For small to medium size networks
(up to 50 Sites)

SIDRA NETWORK Model Features

- ❖ **LANE-BASED** analytical Network model
- ❖ **QUEUE SPILLBACK** and **Capacity Constraint**
- ❖ **Movement Classes**
(special use for downstream turning movements)
- ❖ **Second-by-second lane-based platoon model**
- ❖ **Lane Movements** at intersections
- ❖ **Implied midblock lane changes**
- ❖ **Network signal timing**
(cycle time, green splits and offsets for signal coordination)
- ❖ **Common Control Group** for signal phasing and timing with one signal controller unit

Lane Blockage and Capacity Constraint

Backward spread of congestion (reduced upstream capacity)

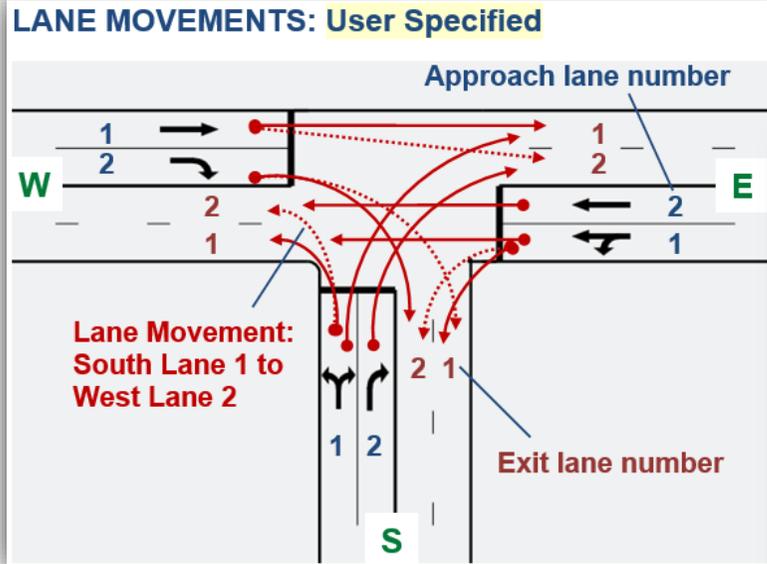

Capacity constraint (reduced downstream arrival flows)

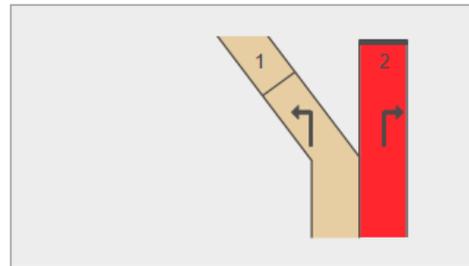

- ❖ The two basic elements of the model are **highly interactive with opposing effects**.
- ❖ Requires an **iterative process** to find a solution that balances these opposing effects (some **uncertainty** for congested networks).
- ❖ **Backward spread of congestion and capacity constraint** are common to all intersection types.

Lane Movements by Movement Class

Lane Editor

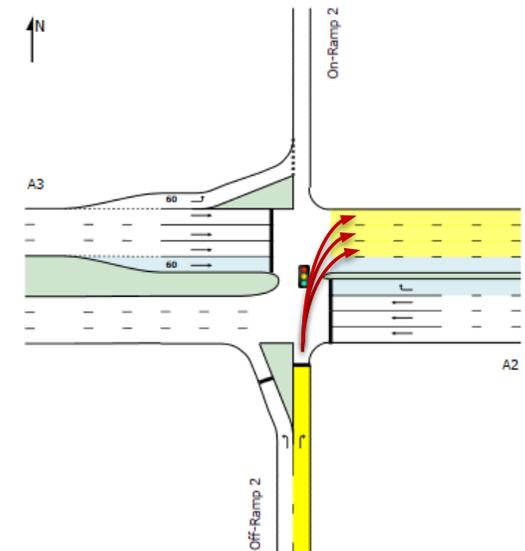

South Approach Lane 2

Lane Movement Flow Proportions

| From South to Exit: | E |
|---------------------|---|
| |  R2 |
| Exit Lane 1 | 33 % |
| Exit Lane 2 | 34 % |
| Exit Lane 3 | 33 % |
| Exit Lane 4 | 0 % |

Freeway Off-ramp Lane Example

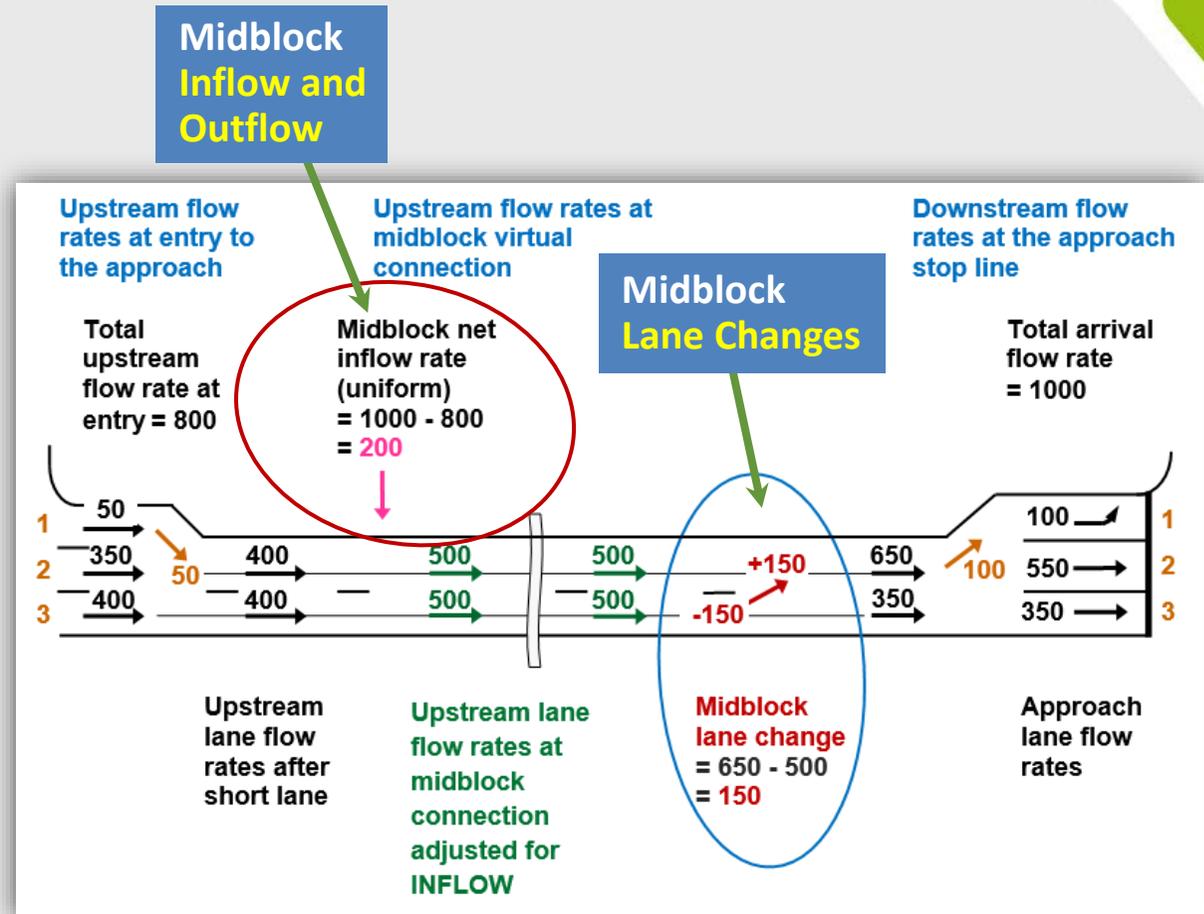

Midblock Lane Changes

Matching of Upstream and Downstream Lane Flow Rates:

- Implied **midblock lane changes**
- Effect of this on **platoon arrival patterns at signals**

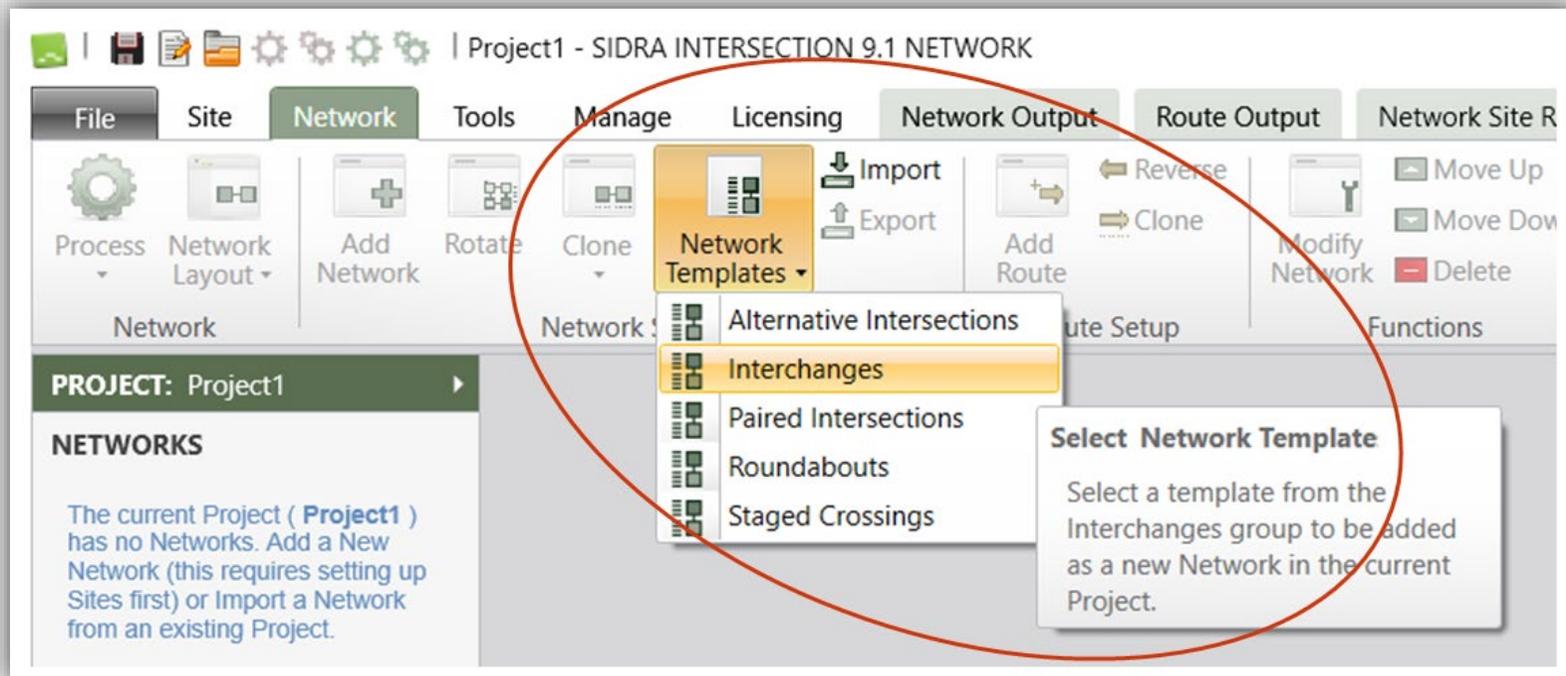

Tools to minimise midblock lane flow changes on short internal approaches:

- **Special Movement Classes**
- **Lane Movement Flow Proportions**
- **Lane Utilisation Ratios**

Network Templates

Network Templates are accessed using the **Network Templates command menu** in the Network tab ribbon.

Variable Demand Model

Variable Demand Model for Congestion Modelling - The **SIDRA Method**

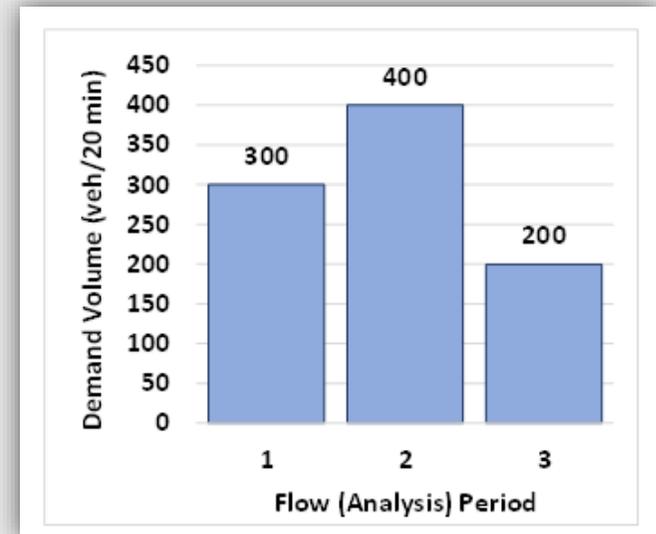

What is Variable Demand Modelling?

The **Variable Demand Model** is useful for **multi-period analysis** of persistent congestion.

The model uses the **Initial Queued Demand** in estimating delays, queue lengths and stop rates when **sequential flow periods** are analysed in cases of **congested conditions**.

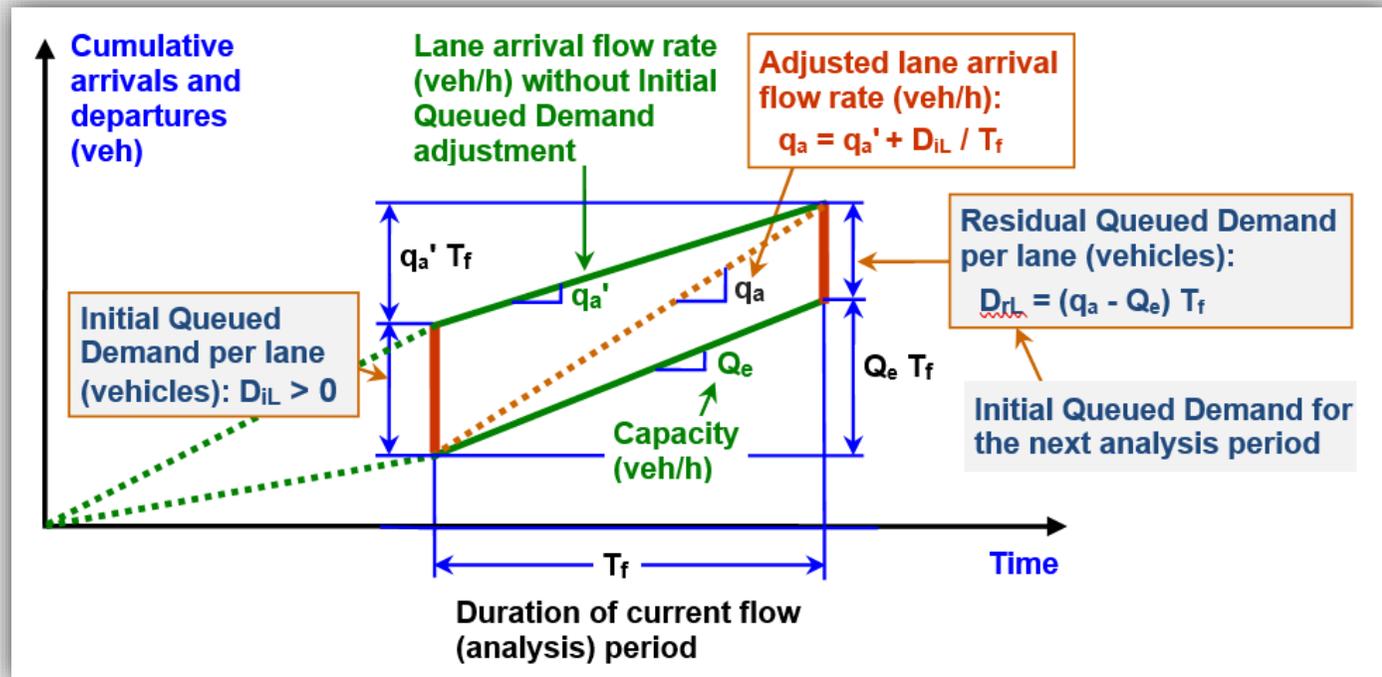

Initial Queued Demand is the **Residual Queued Demand** left over from the **previous flow (analysis) period** when a lane is oversaturated (arrival flow exceeds capacity).

This is shown in the next slide.

Initial and Residual Queued Demand

Deterministic queuing theory is used to formulate a deterministic oversaturation delay function. Initial Queued Demand, Residual Queued Demand and Adjusted Arrival Flow Rate are shown here.

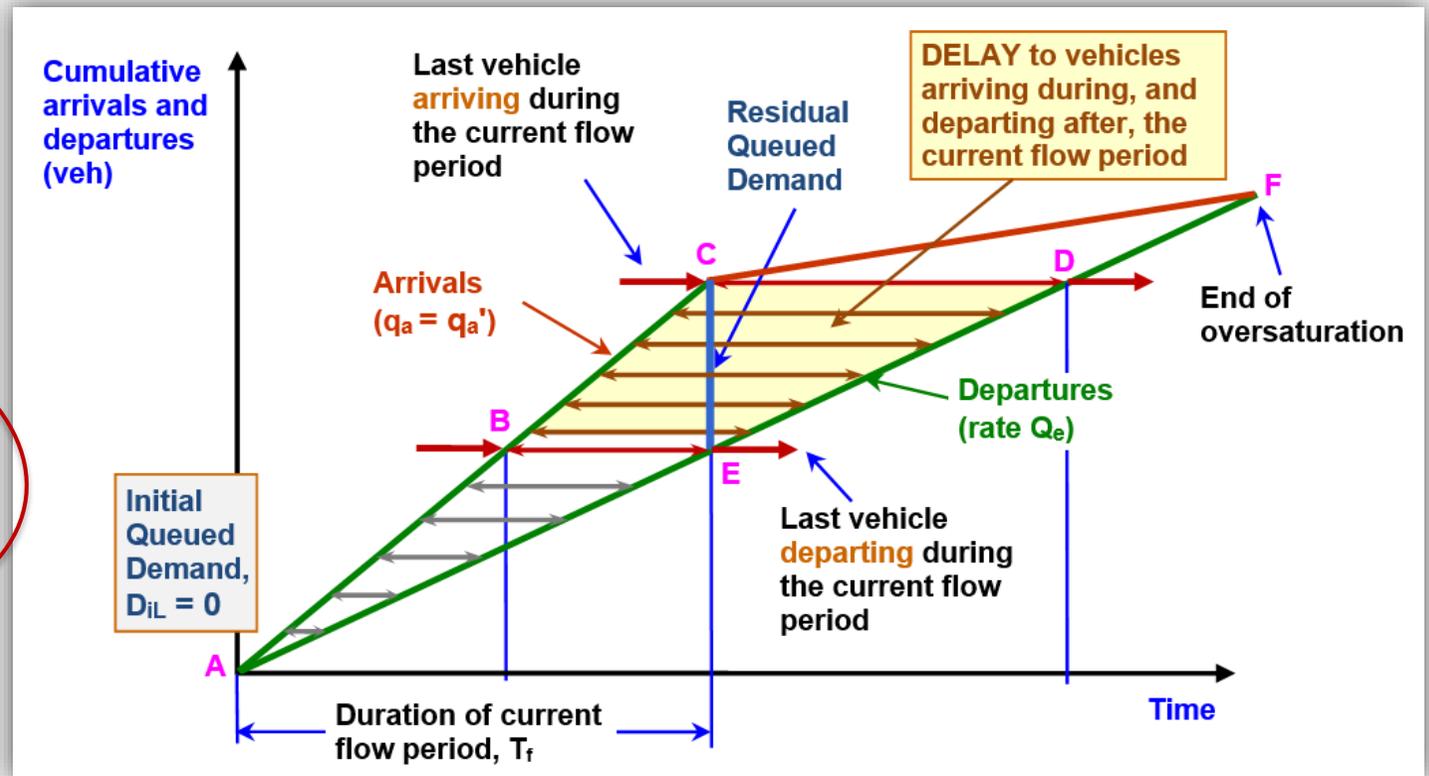

Delay experienced by vehicles in oversaturated conditions: No Initial Queued Demand

Deterministic Oversaturation Delay Model With No Initial Queued Demand

In SIDRA, delay experienced by vehicles departing after the analysis period is **included**.

This corresponds to **in-stream travel time survey method**.

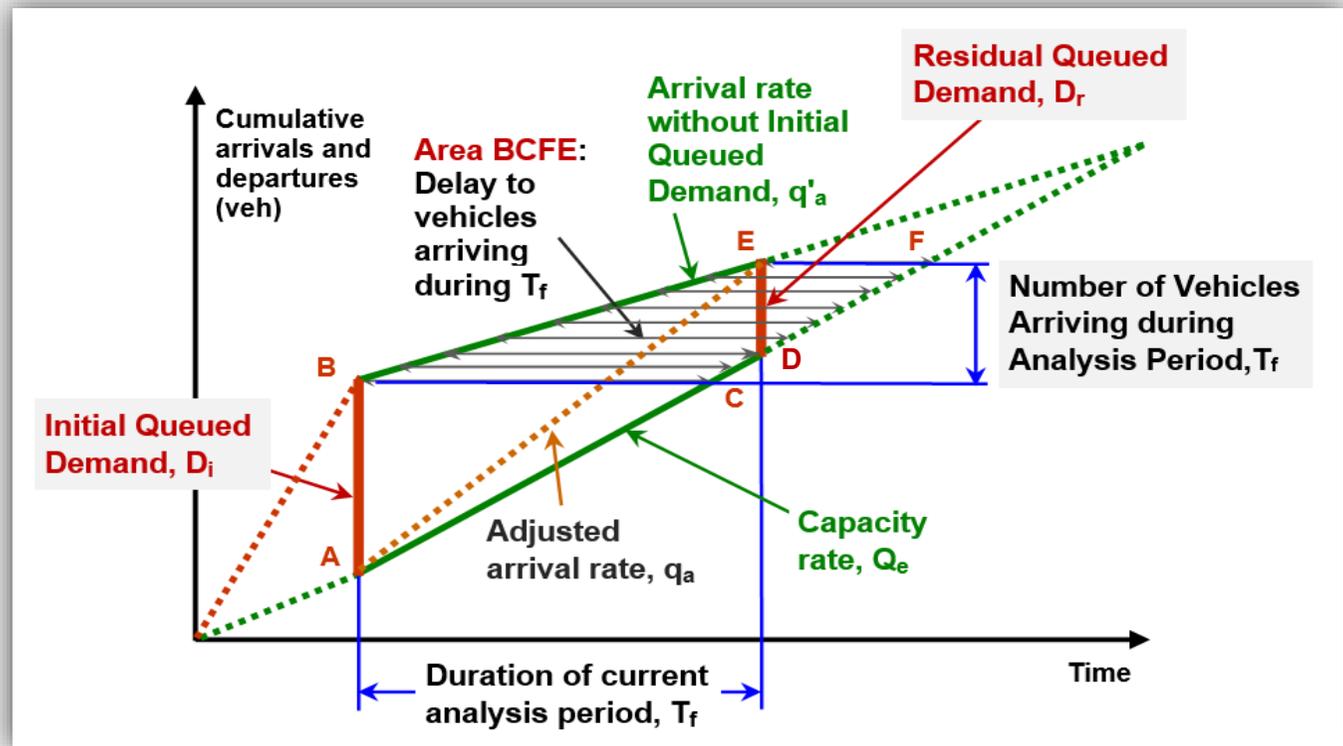

Delay experienced by vehicles in oversaturated conditions

Deterministic Oversaturation Delay Model With Initial Queued Demand

Area ABC: Delay experienced by vehicles arriving before the current flow period (forming the Initial Queued Demand) and departing during the current period; included in delay estimated for the previous flow period.

Area DEF: Delay experienced by vehicles arriving during the current flow period and departing after the current period.

Area BCFE: Delay to vehicles arriving during the current flow period.

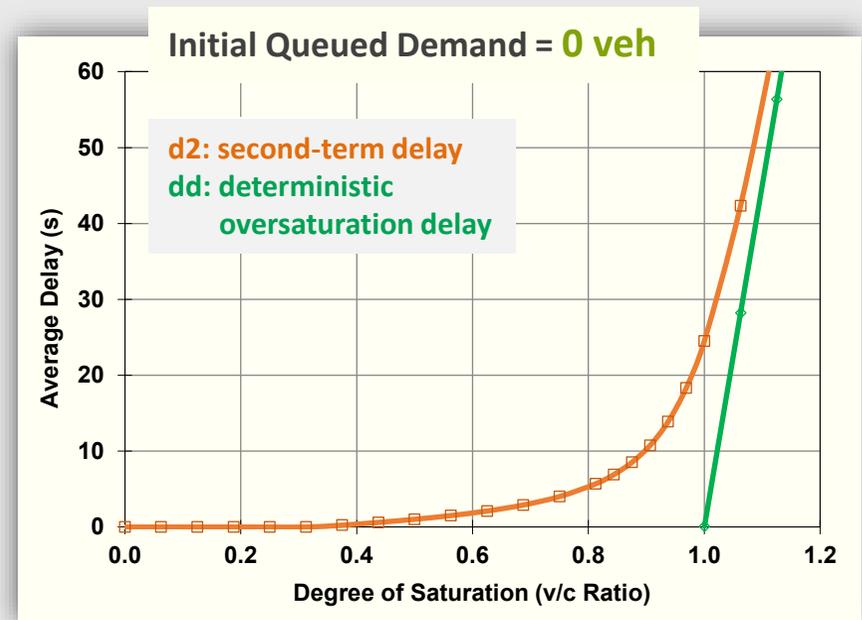

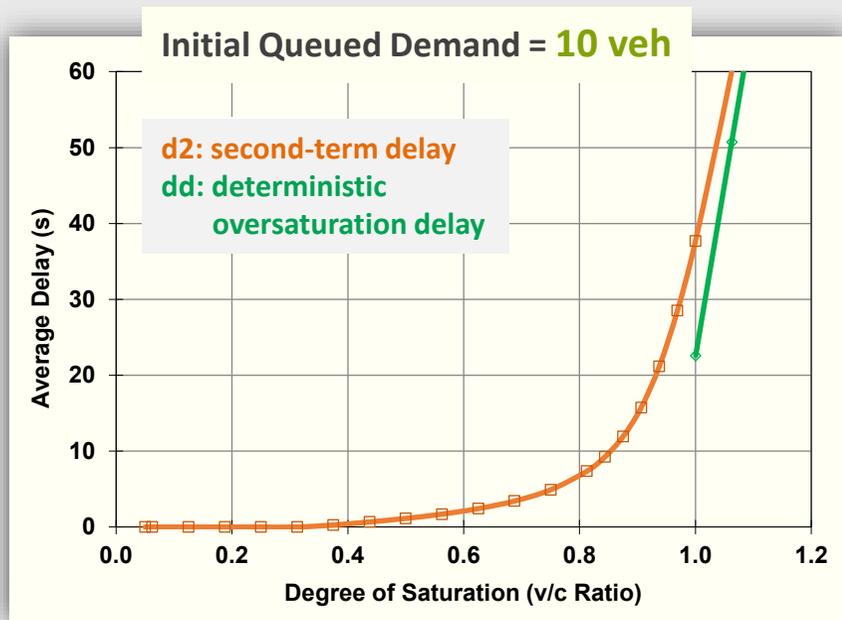

Delay function using the *coordinate transformation technique*

New two-term performance functions have been derived for the Variable Demand Model used in SIDRA INTERSECTION 9.1 using the **coordinate transformation technique**.

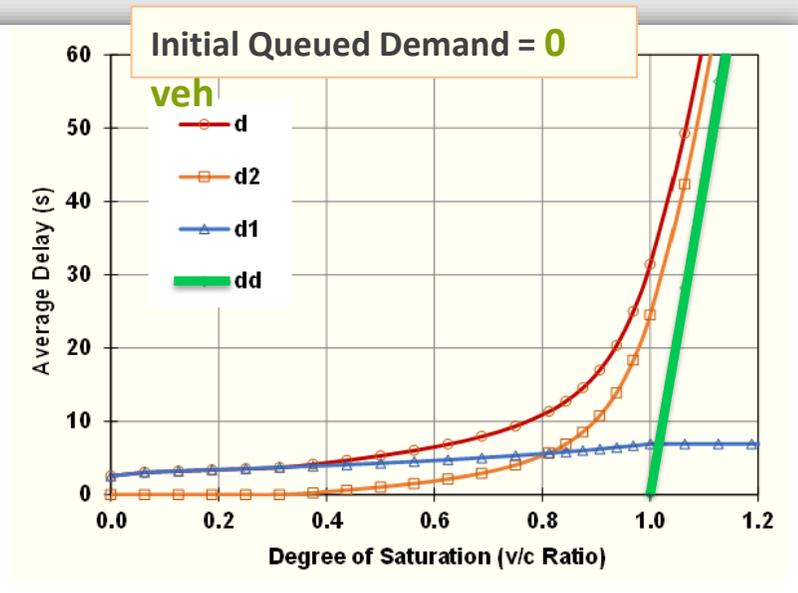

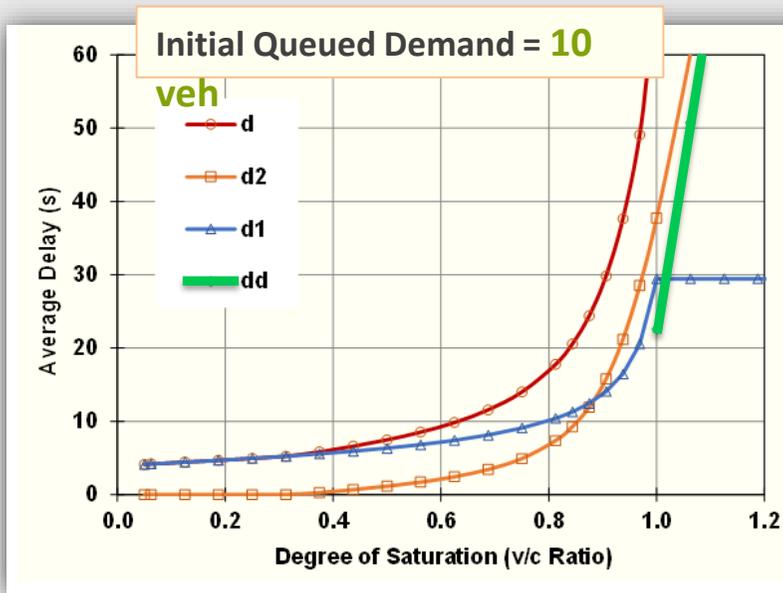

In this method, the **second-term delay function** (time-dependent congestion term) is asymptotic to the **deterministic oversaturation delay function**.

This is the technique used for deriving the models given in **ARR 123** (Akçelik 1981).

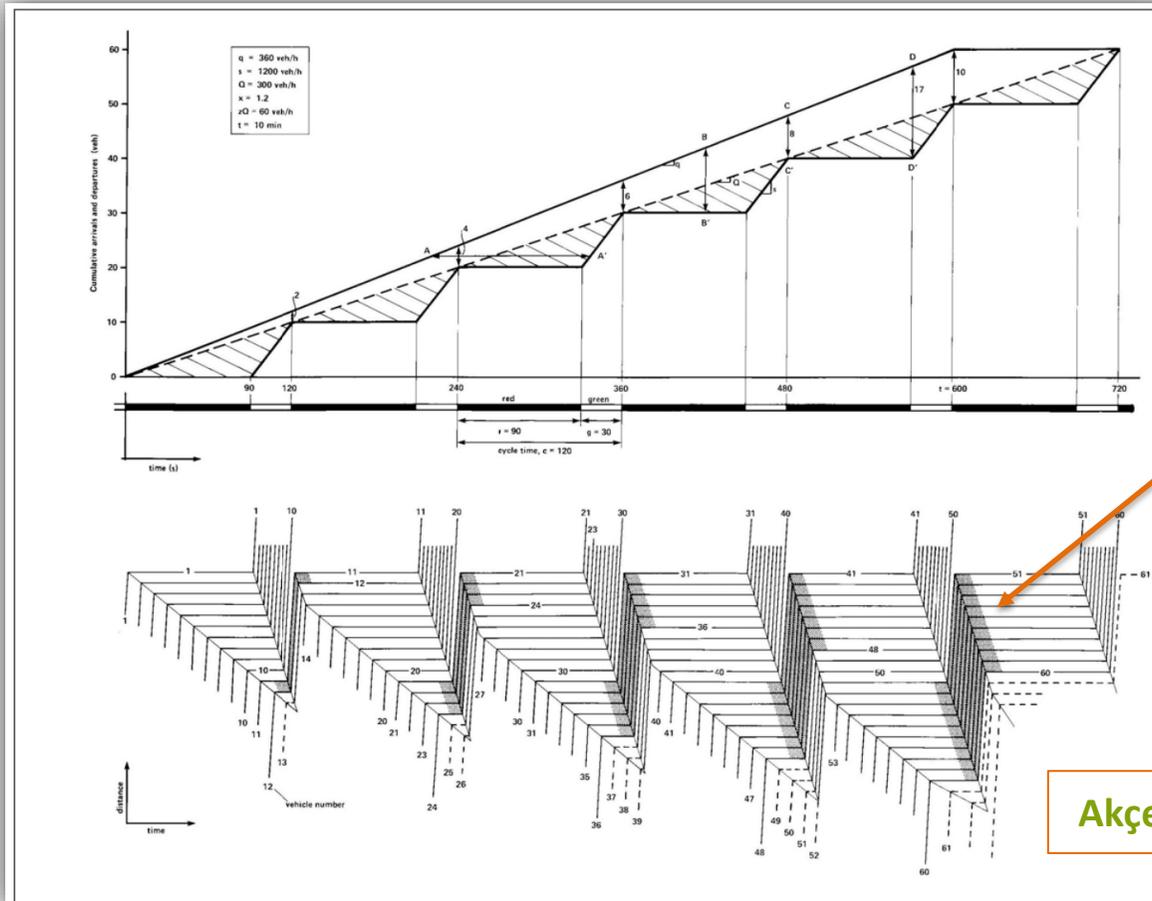

Two-term Performance Function

Example of delay function for a roundabout case with and without Initial Queued Demand (Capacity = 800 veh/h, Flow Period = 0.25 h)

d = d1 + d2: average control delay
d1: first-term delay (red time or blocked time effect)
d2: second-term delay (congestion effect)
dd: deterministic oversaturation delay

Deterministic queuing theory for oversaturation delay and back of queue

Overflow Queues are used in SIDRA performance models

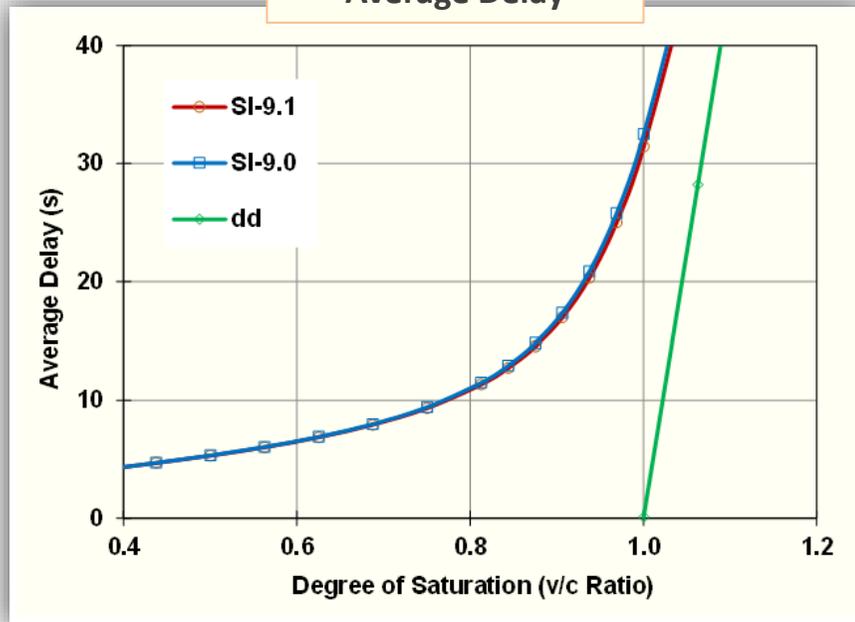

Akçelik (1980)

Average Back of Queue

Initial Queued Demand input in SIDRA INTERSECTION 9.1

Import Initial Demand function is used to copy **Residual Queued Demand** values from the Site representing the previous (15-min) flow period as the **Initial Queued Demand** values for the current Site

The screenshot displays the SIDRA software interface for 'LANE GEOMETRY - Wellington St South Int2 (Site Folder: 7.45 to 8.00 am - CCG)'. The 'Approach Lane Data' section for 'East Approach Lane 2' is visible, showing a value of 141.2 veh for 'Initial Queued Demand'. A red circle highlights this value, and a red arrow points from the 'Import Initial Demand' button in the 'Lane Editor' to the 'Import Initial Demand' dialog box. The dialog box is open, showing the 'Select From:' options: 'Single Sites' (unselected) and 'Network Sites' (selected). The 'Network' dropdown is set to '7.30 to 7.45 - CCG' and the 'Site' dropdown is set to 'Wellington St South Int1'. The dialog box also contains a note: 'Initial Queued Demand values for all lanes will be imported from the selected Site representing the previous flow (analysis) period.' and buttons for 'Help', 'OK', and 'Cancel'.

| Travel Distance | m | 1000 | 1000 | 2000 | 4000 |
| Cruise Speed | km/h | 72 | 72 | 72 | 72 |
| Cruise Travel Time | sec | 50.0 | 50.0 | 100.0 | 200.0 |

Variable Demand Model Example for a Basic Network with three 20-min flow periods

This example shows the **complexity** added to the **variable demand model** for Networks due to **Capacity Constraint** requirements.

Three consecutive **20-min flow periods** analysed for a simple network of three Sites.

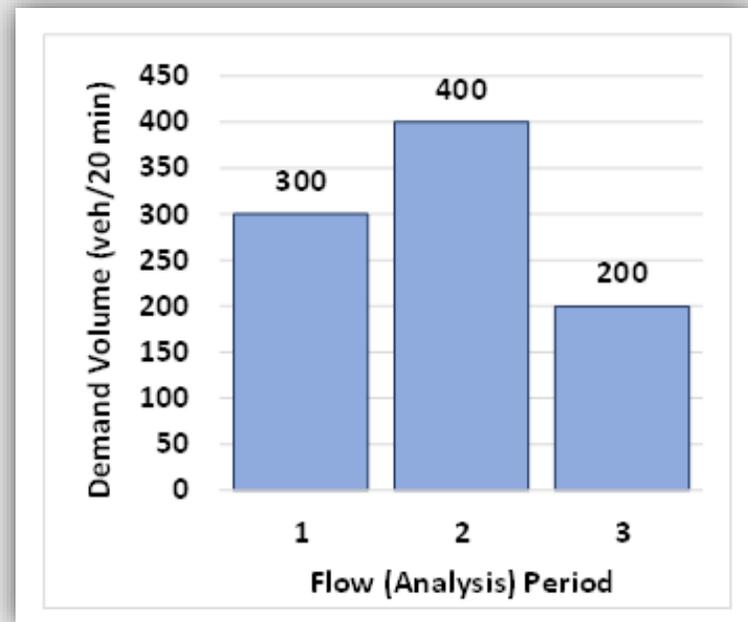

Average Flow Rate per hour: **900 veh/h**

Peak Flow Rate per hour (Period 2):

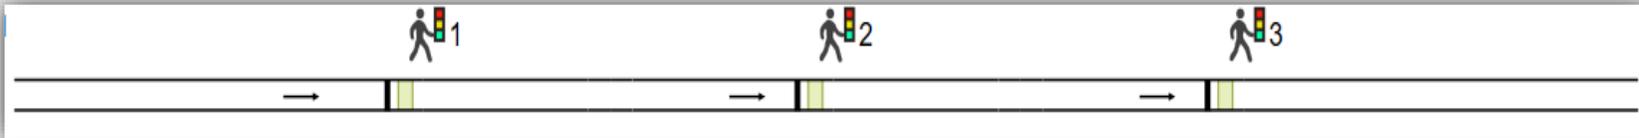

$$(60/20) \times 400 = 1200 \text{ veh/h}$$

Peak Flow Factor:

$$\text{PFF} = 900/1200 = 0.75 \text{ (a high peaking value)}$$

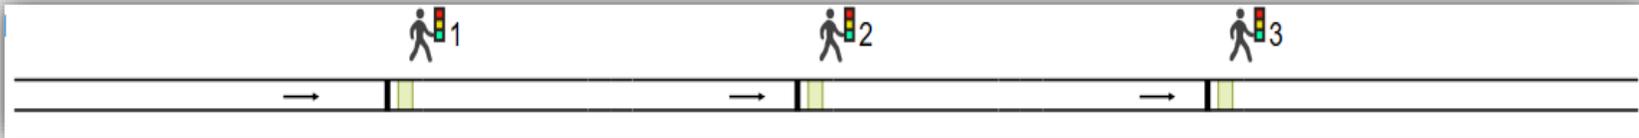

Basic Network - Analysis Period 1

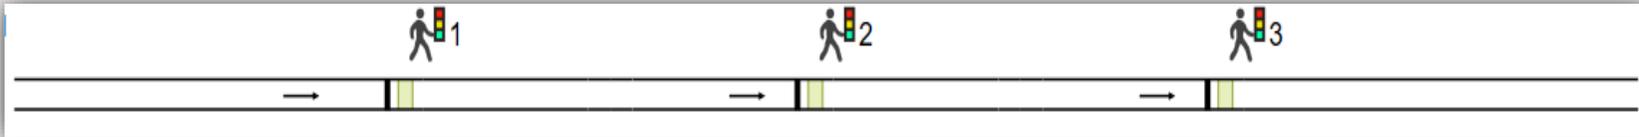

| Analysis Period 1 | | Site 1 | Site 2 | Site 3 | Route |

Previous study

Previous study (Yumlu, Moridpour, Akçelik 2014) reported the analysis of a single Site (Alexandra Pde - Wellington St intersection) and a single peak period (7.45 - 8.00 am).

In the current study:

- A Network model of Alexandra Pde intersections with Wellington St and Smith St. Signals are coordinated.
- 15-min demand flow rates starting at 5.00 am on 5 March 2014 were used to determine the Residual Queued Demand profile.
- Variable Demand Model was applied to four 15-min flow intervals for the 7.30 - 8.30 am flow period. This was used to determine the Initial Queued Demand at the start of 7.30 am peak period (367 veh).
- Results are presented for the 7.45 - 8.00 am period (observed and estimated Back of Queue values compared).
